

Theory of Strings

Robert M. Keller
Harvey Mudd College
2 September 2003

Why are we doing this?

- Strings are **fundamental** to most formal systems (e.g. grammars).
- Strings **generalize** natural numbers (which are themselves very important) in a very natural way.
- Strings are **easy** to work with compared to set-theoretic definitions of natural numbers.

Informal Definition of Strings

- A string is just a sequence $x_1x_2\dots x_n$ where $n \geq 0$.
- The elements of a string are called "letters" or "symbols", but they could be members of any set.
- While infinite strings are sometimes used, for now we will be working only with finite strings.

Formal Definition of Strings

- A string over the set of letters Σ is any member of the following inductively defined set, named Σ^* :
 - The empty string, ϵ , is in Σ^* .
 - If a string x is in Σ^* , and a is in Σ , then ax is in Σ^* .
 - The only elements of Σ^* are those obtained by applying the above rules.
- By Σ^*x we mean a combination of Σ^* with x in such a way that both can be recovered from the result. This can be informally thought of as the "followed by" operator (similar to $[\Sigma^* \mid x]$ in the rex language).

Notes on the Empty String

- The empty string symbol ϵ (upper-case lambda) is a "meta symbol" and as such is never an ordinary letter in Σ .
- Other symbols are often seen in place of ϵ :
 - λ (lower-case lambda) is used in CS 60.
 - ϵ (lower-case epsilon) used in some texts.

Notes on Σ^*x as an ordered-pair

- Effectively this designates an "ordered-pair" of Σ^* with x , which could be written more verbosely as (Σ^*, x) .
- It is a pair because two things are combined.
- It is ordered because (Σ^*, x) is not the same thing as (x, Σ^*) . (In fact, the latter is not meaningful in the current context.)

Ordered-Pairs as Sets

- There are ways of defining the ordered pair concept from more basic, set-theoretic, operations.
- A standard one is that **every pair (x, y) abbreviates a set $\{\{x\}, \{x, y\}\}$** .
- The key thing here is the assurance of the property:

$(x, y) = (x', y')$ implies $x = x'$ and $y = y'$

i.e. that pairs are **decomposable** into their parts.
- This can be proved.

Proof that $(x, y) = (x', y')$ implies $x = x'$ and $y = y'$

- Assume $(x, y) = (x', y')$.
- So $\{\{x\}, \{x, y\}\} = \{\{x'\}, \{x', y'\}\}$.
- If $x = y$, then the LHS is really the same as $\{\{x\}\}$, a set of one element. So the RHS must also be a set of one element, which is to say that $\{x'\} = \{x', y'\}$. But this can be true only if $x' = y'$. We have $\{\{x\}\} = \{\{x'\}\}$. Since these are sets of one element, the elements must be equal, so $\{x\} = \{x'\}$. By the same argument, $x = x'$. Combining with $x = y$ and $x' = y'$, we see that $y = y'$.
- If $x \neq y$, then the LHS is a set of two elements, and therefore the RHS is also. But $\{\{x'\}, \{x', y'\}\}$ is a set of two elements only if $x' \neq y'$. Since $\{x, y\}$ and $\{x', y'\}$ are now known to have two elements, while $\{x\}$ and $\{x'\}$ have one, we conclude that $x = x'$. Then we are led to conclude that $y = y'$, for if not, the two sets of two elements could not be equal, so neither could the original two sets.

Something to Think About

- In our previous argument about pairing, we appealed to certain ideas about sets.
- How can we capture those ideas succinctly as axioms, so that we can articulate exactly what we are using about sets?

Notes on \square and pairing

- \square is not a pair (\square is the only such string with this property).
- \square could be equated to the empty set.
- Example: The string `abc` is constructed as pairs `(a, (b, (c, \square)))`.
- As sets, this would be:

$$\{\{a\}, \{a, \{\{b\}, \{b, \{\{c\}, \{c, \{\}\}\}\}\}\}$$
- Now you can see why we prefer the string notation.

String Concatenation

- Concatenation means "chaining together", i.e. following one string by another.
- Concatenation will be shown by juxtaposition: `xy` is `y` concatenated to `x`.
- Some texts take concatenation as a primitive, given, operation.

String Concatenation

- Concatenation is a function or binary operator on Σ^* and is defined inductively:
 - $\square y = y$ basis
 - $(\square x)y = \square(xy)$ induction step
- On the left-hand sides above is the thing we are defining, and on the right how we are defining it.
- This can be seen as analogous to defining *append* in *rex*.

Why define by induction?

- Definition by induction is **precise**, compared to other alternatives.
- Definition by induction enables **proof** by induction.

String Axioms

- These axioms characterize strings, analogously to the way in which the Peano axioms characterize the natural numbers.
- In the following x, y, \dots are implicitly quantified over strings
- \square, \square', \dots are implicitly quantified over letters.

String Axioms

- SA1: $(\square x)$ (Either $x = \square$ or $(\square\square)(\square y) x = \square y$)
- SA2: $(\square x)$ $(\square\square) \square x \neq \square$
- SA3: $(\square x, x')$ $(\square\square, \square')$
 $\square x = \square'x'$ implies $\square = \square'$ and $x = x'$
- SA4: Let P be any predicate on \square^* .

$$\frac{\text{basis } P(\square), \quad \text{induction step } (\square\square)(P(x) \square (\square\square)P(\square x))}{(\square x) P(x)} \text{infer}$$

- SA4 is a "rule of inference", allowing to prove properties by induction.

Example of Inductive Proof

- ST1: $(\square x) x\square = x$, in other words, \square concatenated to any string is just that string.
- For proof, we identify $P(x)$ in SA4 with $x\square = x$.
- SA4 says that ST1 follows if we can show two things:
 - $P(\square)$, i.e. $\square\square = \square$. basis
 - $(\square x)(P(x) \square (\square\square)P(\square x))$,
 i.e. $(\square x)(x\square = x \square (\square\square) (\square x)\square = (\square x))$ induction step
- How are these two statements shown?

What we don't need to prove

- ST1': $(\square x) \square x = x$

This looks very similar to ST1, but we don't need to prove it. Why?

Another Example of Inductive Proof

- ST2: $(\square x, y, z) x(yz) = (xy)z$. In other words, concatenation is associative.
- Here we identify $P(x)$ in SA4 with $x(yz) = (xy)z$.
- SA4 says that ST2 follows if we can show two things:
 - $P(\square)$, i.e. $\square(yz) = (\square y)z$. basis
 - $(\square x)(P(x) \square (\square\square)P(\square x))$,
 i.e. $(\square x)(x(yz) = (xy)z \square (\square\square) (\square x)(yz) = ((\square x)y)z)$ induction step
- How are these two statements shown?

Defining String Reversal

- We want to define inductively reversal (R operator)
- Here's an intuitively-correct idea:
 - $\square^R = \square$ basis
 - $(\square x)^R = x^R \square$ induction step
- Note: We have to use $\square x$ rather than just \square because $x^R \square$ is not defined. But since $\square x$ is a string, we can concatenate.
- Note that we are using concatenation to define this operator. This could be considered somewhat heavy-handed.

Defining String Reversal

- Another option would be to use an auxiliary function r :
 - $x^R = r(x, \square)$, where
 - $r(\square, y) = y$ basis
 - $r(\square x, y) = r(x, \square y)$ induction step
- Here we haven't used any overt concatenation, and this makes us feel better.
- Note that this is the familiar rex definition in disguise.
- We could now try to prove that the two versions of reversal are equivalent. We'll table this.

Proving stuff about reversal (R operator)

- ST3: $(xy)^R = y^R x^R$
 - Try induction with $P(x): (\square y)(xy)^R = y^R x^R$
 - Basis: $P(\square): (\square y)(\square y)^R = y^R \square^R$
 - Induction step: $(\square y)(\square x)^R = y^R x^R$
- implies $(\square \square)(\square y)(\square x)^R = y^R (\square x)^R$
- | | | |
|--|---|-------------------|
| <ul style="list-style-type: none"> LHS of = is: $(\square \square)(\square y)^R$ $= (\square(\square y))^R$ $= (xy)^R (\square \square)$ $= (y^R x^R) (\square \square)$ | } | Justify each step |
| <ul style="list-style-type: none"> RHS of = is: $y^R (\square x)^R$ $= y^R (x^R (\square \square))$ $= (y^R x^R) (\square \square)$ | | |

Free the Monoids!

- Algebraically, \square^* is known as the "free monoid generated by \square ".
(usually serves to deter the casual reader from going any further)
- Recall that a monoid is a set together with:
 - An associative operator
 - An identity for the operator
- Identify the components that justify calling \square^* a monoid.

Natural Numbers

- Pick \square to be any 1-letter alphabet. (e.g. use \emptyset as a letter).
- Then \square^* is essentially the set of natural numbers:
 - \square is like 0
 - $\square x$ is like $x+1$
- The string axioms are then equivalent to the Peano axioms.
- The induction rule is the usual mathematical induction principle.

Natural Numbers

- Addition is just concatenation over \square^* .
- What are subtraction, multiplication, etc.?
- You'd need to define them inductively: more on this later.

Natural Numbers from Zip

- 0 is \emptyset basis
- $n+1$ is $n \cup \{n\}$ induction step

for example

- 1 is $\emptyset \cup \{\emptyset\}$ which is $\{\emptyset\}$ which has 1 element
- 2 is $\{\emptyset\} \cup \{\{\emptyset\}\}$ which is $\{\emptyset, \{\emptyset\}\}$ which has 2 elements
- 3 is $\{\emptyset, \{\emptyset\}\} \cup \{\{\emptyset, \{\emptyset\}\}\}$ which is $\{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}\}$ which has 3 elements, etc.
- ...
- Let \mathbb{N} designate the set of natural numbers.

The Length $| \cdot |$ of a String

- $|\epsilon| = 0$ basis
- $| \alpha x | = | \alpha | + 1$ induction step

Some Properties of Length

- L1: $|xy| = |x| + |y|$
- L2: $|x^R| = |x|$

Theory of Languages

Robert M. Keller
Harvey Mudd College
2 September 2003

Definition of the Concept "Language"

- A **language** over an alphabet Σ is any subset of Σ^* .
- Give some precise examples of languages.

Operations on Languages

- Since languages are sets, we can define their **union**, **intersection**, etc. just as with any sets, e.g.
- Let L and M be two languages.

$$\begin{aligned}L \cup M &= \{x \mid x \in L \text{ or } x \in M\} \\L \cap M &= \{x \mid x \in L \text{ and } x \in M\} \\L - M &= \{x \mid x \in L \text{ and } x \notin M\}\end{aligned}$$

Product of Languages

- Let L and M be two languages. Define

$$LM = \{xy \mid x \in L, y \in M\}$$

called the "product" or (loosely) the "concatenation" of languages.

- Give examples.
- What if either is \emptyset ?

Power Operator for Languages

- L be a language. Define the " n^{th} power" of L inductively:

$$L^0 = \{\epsilon\}$$

$$L^{n+1} = L L^n$$

- Examples?

Plus and Star Operators for Languages

- L be a language. Define

$$L^* = L^0 \cup L^1 \cup L^2 \cup \dots$$

- Define

$$L^+ = L^1 \cup L^2 \cup L^3 \cup \dots$$

- Thus

$$L^* = \{\epsilon\} \cup L^+$$

- Give examples.

L^* vs. Σ^*

- They are the same, provided that L is the set of 1-letter strings, one for each letter in Σ .

Language Identities: Devise RHS's

- $L\emptyset =$
- $L\{\epsilon\} =$
- $(LM)N =$
- $LL^* =$
- $LL^+ =$
- $\{\epsilon\}^* =$
- $\{\epsilon\}^+ =$
- $\emptyset^* =$
- $\emptyset^+ =$
- $(L \cup M)N =$
- $(L \cup M^*)^* =$
- $(LM^*)^* =$

Solving a Language Equation

- This will be seen to be a useful device shortly:
- The equation $L = LA \cup B$ has as a solution for L :

$$L = BA^*$$

- How can we justify this?

Regular Operators and Languages

- Union, Star, and Product (Concatenation) are called the **Regular Operators** on Languages.
- A language is **regular** if it can be formed from languages consisting of only one string of one letter each using a **finite** number of regular operators.
- Note: * counts as only one operator, despite it being defined as an infinite union.
- Examples of Regular Languages?

True or False?

- Any language of exactly one element is regular.
- Any finite language is regular.
- Σ^* - L, where L is finite, is regular.
- Every language is regular. To see this, let $L = \{x_1, x_2, x_3, \dots\}$.
Then $L = \{x_1\} \cup \{x_2\} \cup \{x_3\} \cup \dots$, which is clearly regular.

Regular Expressions

- A regular expression is a **shorthand** way of representing regular languages using regular operator symbols in conjunction with the following symbols.
- Each letter a in Σ stands for the language with just one string of one letter, that letter.
- Σ stands for the language $\{\Sigma\}$.
- \emptyset stands for the empty language \emptyset .
- Example: If $\Sigma = \{0, 1\}$, then 0 stands for the language with just one string, having one letter, 0.

Examples of Regular Expressions

- $0 \cup 1$
- $(0 \cup 1)^*$
- $(0 \cup 1)0^*1^*$
- $((0 \cup 1)0^*1)^*$
- $((0 \cup 1)0^*1)^*$
- $0^*110^* \cup 1^*001^*$

Regular Expression Notation Notes

- Instead of \cup , some sources use infix + or | in regular expressions.
- * binds the tightest, then concatenation, then \cup .
- \cup is not a regular operator, nor is -.

Regular Expressions as Patterns

- Any language can be equated to a "pattern", namely the pattern that matches all strings in the language.
- Examples:
 - 0^* is the pattern that matches strings containing only 0's
 - 0^*10^* is the pattern that matches strings in $\{0, 1\}^*$ containing exactly one 1.
 - 0^*100^* is the pattern that ...
 - $0(0 \cup 1)^*1$
 - $((0 \cup 1)(0 \cup 1))^*$
 - $(0 \cup 1)(10)^*(1 \cup \emptyset)$
- Note: To qualify as a pattern, the language of the expression must be that of **exactly** the set of strings matching the pattern, not a subset or superset.

Regular Expressions as Patterns

- Give regular expressions for the following patterns over $\{0, 1\}$:
 - Strings in which each 1 is followed by a 0.
 - Strings in which no 1 is followed by a 0.
 - Strings in which every 1 is preceded by and followed by a 0.
 - Strings in which the number of 1's is divisible by 3.
 - Strings in which there is no run of 3 consecutive 1's.

Application: Searchers

- Do `man` `egrep` on a UNIX system.
- How do such search algorithms work?

Finite-State Automata

Robert M. Keller
Harvey Mudd College
2 September 2003

Automata

- Colloquially, an **automaton** (plural "automata") is an autonomous device (such as a robot or wind-up toy).
- In CS, the term has a more specific meaning: that of an abstract **mathematical machine** that can perform a specific function.

Uses of Automata

- There are many uses, one of which is to specify algorithms for accepting languages.
- An automaton **accepts a language** if it can tell, for any given input string, whether or not the string is in the language.

Example: Compilers, etc.

- Every compiler contains an automaton, that tells whether or not the input string is well-formed, i.e. is in the language that it compiles.
- Every pattern search program is effectively an automaton for recognizing patterns.

Finite-State Automata (FSA or DFA, they are the same)

- An automaton is finite-state if its behavior is representable by transitions between a states in a finite set, some of which are designated accepting and others not.
- Each automaton has a designated start state.

Examples of FSA

- An FSA capable of accepting exactly the strings ending with 1.

Examples of FSA

- An FSA capable of accepting exactly the strings containing no two consecutive 1's.

Thing to Check

- For each combination of a state and a symbol, there should be exactly one arrow leaving the state with that symbol.
- This is the "deterministic" ("D") in DFA.
- If this property does not hold, better fix it; your automaton might be wrong.

Application

- One way to implement a search is to construct, perhaps on the fly, an automaton that accepts the corresponding language, then simulate the automaton on the given input.

Two Ways to Define Specific Languages

- Give an FSA that accepts the language.
- Give a regular expression for the language.

Remarkable Fact

- The preceding two ways are equivalent.
- Equivalent here means that the two methods define the same family of languages.

Application of this Theory

- Sometimes it's easier to give an automaton for a language.
- Sometimes it's easier to give a regular expression.
- It would be nice to be able to go from one to the other more-or-less freely.

Regular Expression from FSA

- Label the States

- Identify each state with the set of paths from the start state to it. This set is a language.
- The language accepted by the FSA is the **union** of the paths to each of the accepting states, in this case $L \cup M$.

Deriving Closed Forms

- View the acceptor as a set of **regular-expression equations**:

- $L = L0 \cup M0 \cup \epsilon$
- $M = L1$
- $N = M1 \cup N(0 \cup 1)$
- The ϵ is on the RHS of the starting state only.
- We want to solve for L and M, and take the union of the solutions.

Solving RE Equations

- **Solve** for L and M:
 - $L = L0 \cup M0 \cup \epsilon$
 - $M = L1$
 - $N = M1 \cup N(0 \cup 1)$
- **Substitution** Operation:
 - A LHS variable can be replaced with its RHS, so replacing M in the L equation:
 - $L = L0 \cup L10 \cup \epsilon$, or more simply
 - $L = L(0 \cup 10) \cup \epsilon$
- **Elimination** Operation:
 - An equation of the form $L = LA \cup B$ has the solution $L = BA^*$, so:
 - $L = (0 \cup 10)^*$, or more simply $L = (0 \cup 10)^*$
- **Substitution** again:
 - $M = L1$
 - $M = (0 \cup 10)^*1$

Conclusion

- The language accepted by the FSA below is
 - $L \cup M$
 - which is $(0 \cup 10)^* \cup (0 \cup 10)^*1$
 - or more simply
 - $(0 \cup 10)^*(0 \cup 1)$

FSA \rightarrow RE Algorithm

- Express the FSA as a set of RE equations
 - Each state is a variable.
 - Each variable is equated to a union of expressions showing how to get to that state in one step from other states.
 - The start state has ϵ on the RHS as well.
- Solve the RE equations for the variables:
 - The variables, along with their equations, are solved for one at a time.
 - Choose a variable for elimination.
 - Expression that variable in terms of the remaining variables only, using the $*$ operator ($L = LA \cup B$ has the solution $L = BA^*$).
 - Substitute the solution for all occurrences of the variable in the remaining equations.
 - Repeat the above steps until no variables remain.
- Work backward, substituting the solutions found for other variables, until each variable is expressed in closed form.

Another Example

- **Solve:**
 - $L = L1 \cup M0 \cup N0 \cup \epsilon$
 - $M = L0 \cup M1 \cup N1$
 - $N = L1 \cup M1 \cup N0$
- Note that these equations don't really correspond to a DFA, but it doesn't matter.
- Eliminate N, using $N = (L1 \cup M1)0^*$
 - $L = L1 \cup M0 \cup (L1 \cup M1)0^*0 \cup \epsilon$
 - $M = L0 \cup M1 \cup (L1 \cup M1)0^*1$
- Regroup:
 - $L = L(1 \cup 10^*0) \cup M(0 \cup 10^*0) \cup \epsilon$
 - $M = L(0 \cup 10^*1) \cup M(1 \cup 10^*1)$

Solution, continued

- Solving:
 - $L = L(1 \cup 10^*0) \cup M(0 \cup 10^*0) \cup \epsilon$
 - $M = L(0 \cup 10^*1) \cup M(1 \cup 10^*1)$
- Eliminate M using $M = L(0 \cup 10^*1) (1 \cup 10^*1)$, giving:
 - $L = L(1 \cup 10^*0) \cup L(0 \cup 10^*1) (1 \cup 10^*1) (0 \cup 10^*0) \cup \epsilon$
- Regrouping:
 - $L = L((1 \cup 10^*0) \cup (0 \cup 10^*1) (1 \cup 10^*1) (0 \cup 10^*0)) \cup \epsilon$
- Solving:
 - $L = ((1 \cup 10^*0) \cup (0 \cup 10^*1) (1 \cup 10^*1) (0 \cup 10^*0))^* \cup \epsilon$
- Working backward:
 - $M = ((1 \cup 10^*0) \cup (0 \cup 10^*1) (1 \cup 10^*1) (0 \cup 10^*0))^* (0 \cup 10^*1) (1 \cup 10^*1)$
 - $N = (L1 \cup M1)0^* = \dots$

Summary so far

- The language accepted by an FSA is a regular language.
- We haven't shown that the converse is true.
