Intro to Logic Programming and the Prolog Language

Bob Keller

November 2009
What is this?

- A type of computation model and declarative programming language.

- Useful for:
  - Language understanding and translation
  - Databases
  - Knowledge representation
  - Artificial intelligence applications
Why study this?

- Expands expressiveness over what we have seen so far.

- A good language for learning about ideas of:
  - certain forms of logic
  - non-determinism
  - backtracking
Who uses Prolog?

- People who want to have a broad set of intellectual and problem-solving tools at their disposal.
Advantages of Succinctness

- Code moves closer to concepts (and farther from machine details).
- Easier to ascertain correctness.
- Easier to modify, for purposes of software evolution.
Prolog’s Origins
(see http://en.wikipedia.org/wiki/Prolog)

- Prolog was invented at the University of Montreal around 1970 by Alain Colmerauer, who since has been professor at the École Supérieure d'Ingénieurs de Luminy in Marseille, France.

- The original work was a grammar-based language for natural language translation.
Varieties of Logic

- **Proposition Logic:**
  - Propositions are symbols which may be assigned one of two values:
    - true
    - false
  - without regard to specific individuals.

- **Predicate Logic:**
  - Predicates can be viewed functions from a domain of individuals to \{true, false\}. 
Comparison

- Propositions:
  - hmc_is_great
  - caltech_is_in_glendale

- Predicates (X and Y are variables)
  - is_great(X)  is_great(hmc)
  - is_in(X, Y)  is_in(caltech, glendale)
Logic of Implication
(Prolog Style)

* Logical rule:
  \[ Q :\text{-} P_1, P_2, P_3. \]
  
  means that proposition or predicate application

  \[ Q \text{ is implied by the conjunction of } P_1, P_2, \text{ and } P_3: \]

  If each of \( P_1, P_2, P_3 \) are true, then \( Q \) is true.

  (However, \( Q \) could also be true even if none of \( P_1, P_2, P_3 \) is.)
Prolog Lingo

- This is a clause:

  \[ Q :\sim P_1, P_2, P_3. \]

- Q is called the **head**.

- P1, P2, P3 is called the **body**.

- Each of Q, P1, P2, P3 are individually called **goals**.
Example Clause

• \texttt{prepared\_for\_exam :- read\_book, worked\_problems, attended\_lectures.}
Example Clause

- prepared_for_exam :-
  knows_it_all.
Example Clause

- prepared_for_exam :-
  tutored_by_someone_prepared.
Facts

- Facts are clauses with an empty body.
- They assert the truth of something without qualification.
Examples of Possible Facts

read_book.
worked_problems.
attended_lectures.
knows_it_all.
tutored_by_someone_prepared.

Depending on the facts present, a goal prepared_for_exam maybe inferred as true or not.
Success and Failure

- A goal is presented interactively to Prolog as:

  ?- prepared_for_exam.

Depending on the facts, this goal may succeed or fail.
Success and Failure

- A goal **succeeds** provided one of:
  - There is a **fact** that matches the goal.
  - There is a **clause**, 
    - the head of which matches the goal, and 
    - all goals in the body succeed.

- [Notice the first blue bullet is really a special case of the second.]

- If a goal doesn’t succeed, then it **fails**.
Success and Failure Examples

- If the facts are:
  
  ```
  read_book.
  worked_problems.
  attended_lectures.
  ```

  and there is a clause:
  
  ```
  prepared_for_exam :-
  read_book,
  worked_problems,
  attended_lectures.
  ```

  then the goal
  
  `?- prepared_for_exam.`

  succeeds. If any of the facts is missing, the goal fails.
Success and Failure Examples

- If the facts are:
  
  ```
  read_book.
  attended_lectures.
  tutored_by_someone_prepared.
  ```

  and there is a clause:
  
  ```
  prepared_for_exam :-
  tutored_by_someone_prepared.
  ```

  then the goal
  
  ```
  ?- prepared_for_exam.
  ```

  succeeds.
How Prolog Works

- In general, there can be several goals, all of which need to succeed.

- Think of these goals as being kept in a stack.

- Success occurs when the stack is empty.

- The first goal is removed from the stack.

- Prolog searches for a clause having a matching head.
  - If none is found, then there is overall failure.
  - If a matching fact is found, then execution continues with the rest of the stack.
  - If a matching clause is found, then the clauses in the body of the clause are pushed onto the stack (with the leftmost goal now at the top) and execution continues with the new list.
When a failure occurs, Prolog does not stop. It goes back to the previous clause it used, and restores the list to the way it was just before. (It “backtracks”.)

It then tries any alternative clauses that follow that clause.

Clauses are tried in the order listed in the program, until there are no more clauses left.

For new each goal, searching starts afresh.
Backtracking Example

Suppose the clauses and facts are:

- `prepared_for_exam :- read_book, worked_problems, attended_lectures.`
- `prepared_for_exam :- tutored_by_someone_prepared.`
- `read_book.`
- `worked_problems.`
- `tutored_by_someone_prepared.`

Consider the goal

`?- prepared_for_exam.`
Backtracking Example

- The initial goal stack is:
  - [prepared_for_exam]
- After a match with the first clause, the stack becomes:
  - [read_book, worked_problems, attended_lectures]
- then, as facts are matched, the stack becomes:
  - [attended_lectures]
- but here there is no matching fact or clause. Backtracking occurs, restoring the list to:
  - [prepared_for_exam]
- The next clause that matches changes the list to:
  - [tutored_by_someone_prepared]
- The first goal matches a fact, leaving:
  - []
- The original goal thus succeeds.
The Two Compatible Interpretations of Prolog Execution

- Logical interpretation:
  - Implications and facts.

- Procedural interpretation:
  - Goals, backtracking, etc.
Prolog’s Negation

- Facts are always asserted in the positive sense.
- Negation can be tested, but not asserted.
- Negation is “negation as failure”:
  \[ +Goal \]
  succeeds iff \( Goal \) fails.
- In classical logic, \( \vdash G \) means “\( G \) is provable”.
  \( + \) is a representation of “is not provable”.

\[ \vdash \]
Negation Example

- The clause
  
  \[
  \text{prepared\_for\_exam} :- \\
  \text{read\_book}, \\
  \text{worked\_problems}, \\
  \text{attended\_lectures}, \\
  \text{\textbackslash+ slept\_during\_lectures}.
  \]

  will enable

  \[
  \text{prepared\_for\_exam}
  \]

  to succeed only if

  \[
  \text{slept\_during\_lectures}
  \]

  does not succeed.
Predicate vs. Propositional Goals

- The goals so far have been propositional:
  - Each is either *invariably* true (succeeds) or false (fails).

- Using predicates, success or failure depends on *arguments*.

- Each fact and clause can have one or more arguments.
Exam Passing for the Full Class

- read_book(fred).
- read_book(judy).
- worked_problems(judy).
- attended_lectures(fred).
- attended_lectures(judy).
- tutored_by(fred, bob).
- tutored_by(sam, judy).
Predicate Form of Exam Passing

\[
\text{prepared\_for\_exam}(X) :- \\
\quad \text{read\_book}(X), \\
\quad \text{worked\_problems}(X), \\
\quad \text{attended\_lectures}(X).
\]

\[
\text{prepared\_for\_exam}(X) :- \\
\quad \text{tutored\_by}(X, Y), \\
\quad \text{prepared\_for\_exam}(Y).
\]
Extreme Case-Sensitivity

- In Prolog,
  - Variables always start with upper-case or underscore.
  - Things that start with lower-case are:
    - Predicates, propositions
    - Data items (atoms): Similar to symbols in Scheme
  - Data items can also start with upper-case if singly-quoted, e.g. 'John Hancock'.
  - Unlike Scheme, '-' is not considered to be just another letter.
Case Sensitivity, Arity

- read_book(fred).
- prepared_for_exam(X) :-
  tutored_by(X, Y),
  prepared_for_exam(Y).

Variables:
  X, Y

Atoms:
  fred

Predicates:
  read_book/1, prepared_for_exam/1, tutored_by/2.

/N indicates the arity (number of arguments) of the predicate. Predicate names can be overloaded.
Matching = Unification

- **Unify** means: “make the same”.
  - Two atoms are unifiable iff identical.

- A variable can be unified with anything (even another variable), by substituting the latter thing for the variable.

- Two predicate expressions can be unified, provided that:
  - The predicate names are identical.
  - The number of arguments is the same in both.
  - Each of the arguments can be pairwise-unified, by a common substitution.
### Prolog Unification Examples

<table>
<thead>
<tr>
<th>Term 1</th>
<th>Term 2</th>
<th>Unifiable?</th>
<th>Substitution</th>
</tr>
</thead>
<tbody>
<tr>
<td>fred</td>
<td>bob</td>
<td>No</td>
<td></td>
</tr>
<tr>
<td>fred</td>
<td>X</td>
<td>Yes</td>
<td>X ← fred</td>
</tr>
<tr>
<td>X</td>
<td>bob</td>
<td>Yes</td>
<td>X ← bob</td>
</tr>
<tr>
<td>X</td>
<td>Y</td>
<td>Yes</td>
<td>X ← Y</td>
</tr>
<tr>
<td>p(X, Y)</td>
<td>p(fred, bob)</td>
<td>Yes</td>
<td>X ← fred</td>
</tr>
<tr>
<td></td>
<td>p(fred, Y)</td>
<td>Yes</td>
<td>X ← fred</td>
</tr>
<tr>
<td>p(X, bob)</td>
<td>p(fred, X)</td>
<td>No</td>
<td></td>
</tr>
</tbody>
</table>
## More Unification Examples

<table>
<thead>
<tr>
<th>Term 1</th>
<th>Term 2</th>
<th>Unifiable?</th>
<th>Substitution</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p(X, X)</code></td>
<td><code>p(fred, bob)</code></td>
<td>No</td>
<td></td>
</tr>
<tr>
<td><code>p(X, f(Y))</code></td>
<td><code>p(Y, Z)</code></td>
<td>Yes</td>
<td>(X \leftarrow Y) (Z \leftarrow f(Y)) (Y \leftarrow f(X))</td>
</tr>
<tr>
<td><code>p(a, f(Y))</code></td>
<td><code>p(Y, Z)</code></td>
<td>Yes</td>
<td>(Y \leftarrow a) (Z \leftarrow f(a))</td>
</tr>
<tr>
<td><code>p(g(Z), f(Y))</code></td>
<td><code>p(Y, Z)</code></td>
<td>Yes (but only in Prolog)</td>
<td>(Y \leftarrow g(f(g(f(\ldots])))) (Z \leftarrow f(g(f(g(\ldots))))</td>
</tr>
</tbody>
</table>
## Quiz 1: Complete the Table

<table>
<thead>
<tr>
<th>Term 1</th>
<th>Term 2</th>
<th>Unifiable?</th>
<th>Substitution</th>
</tr>
</thead>
<tbody>
<tr>
<td>p(X, fred)</td>
<td>p(fred, X)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>p(X, Y)</td>
<td>p(Y, Z)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>p(b, f(b))</td>
<td>p(f(X), b)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>p(a, X)</td>
<td>p(a, f(a))</td>
<td></td>
<td></td>
</tr>
<tr>
<td>p(X, f(Z), Z)</td>
<td>p(a, X, a)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>p(X, Y, Z)</td>
<td>p(f(Y), g(Z), a)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Use = in Command to Check Unifiability

?- p(a, f(Y)) = p(Y, Z).
Y = a,
Z = f(a)
Yes

?- p(X, X) = p(fred, bob).
No

?- p(g(Z), f(Y)) = p(Y, Z).
Z = f(g(**)),
Y = g(f(**))
Yes
Unification and Clause Searching

- The variables of a clause are purely **local** to the clause. Variables do **not** connect one clause to another.

- When **searching for a match**, the variables in a clause are first **renamed** uniformly across the clause so that they are distinct from any variables that might be in the goal.

- Any substitution applied to a **goal** is applied to all remaining goals in the list.
Example

- **Clauses:**
  - `prepared_for_exam(bob).`
  - `tutored_by(fred, bob).`
  - `prepared_for_exam(X) :- tutored_by(X, Y), prepared_for_exam(Y).`

- **Goals:**
  - `[prepared_for_exam(fred)]`

- **Substitution:**
  - `X1 ← fred`

- **New goals:**
  - `[tutored_by(fred, Y1), prepared_for_exam(Y1)]`

- **Substitution:**
  - `Y1 ← bob`

- **New goals:**
  - `[prepared_for_exam(bob)]`
Recursive Example

child(Parent, Child, Graph) :-
    member([Parent, Child], Graph).

isDescendant(Ancestor, Desc, Graph) :-
    child(Ancestor, Desc, Graph).

isDescendant(Ancestor, Desc, Graph) :-
    child(Ancestor, Child, Graph),
    isDescendant(Child, Desc, Graph).

?- isDescendant(e, a, [[a,b], [b, c], [c,d], [b,e], [a,f]]).

Yes
Prolog’s Data Types

- **Atoms**: x, abc, y99, this_is_too
- **Numbers**: 789, 15.3e-27
- **Terms**: f(x, 789)
- **Lists** (special type of term):
  - [red, green, blue]
  - [[red, 10], [green, 20], [blue, 50]]
Variables beginning with _ (including _ itself) are “throw away” or “don’t care”.

They match anything.

They do not need to unify with other instances of the same variable.
Database Applications

- Data are stored as predicate facts (aka “relations”).

- Queries are goals.

- Substitutions (resulting from unifications) are results.
Relational Database Example

<table>
<thead>
<tr>
<th>lives</th>
<th>name</th>
<th>dorm</th>
</tr>
</thead>
<tbody>
<tr>
<td>John</td>
<td>East</td>
<td></td>
</tr>
<tr>
<td>Naima</td>
<td>South</td>
<td></td>
</tr>
<tr>
<td>Alice</td>
<td>West</td>
<td></td>

<td></td>
</tr>
</tbody>
</table>

Three relations:

\[ \text{lives} \subseteq \text{names} \times \text{dorms} \]

\[ \text{takes} \subseteq \text{names} \times \text{depts} \times \text{numbers} \]

\[ \text{tutors} \subseteq \text{names} \times \text{depts} \times \text{numbers} \]
Relational Database Example

Sample Queries:

Who lives in South dorm?

\[ \text{lives}(X, 'South') \]

Who lives in East dorm and takes CS 60?

\[ \text{lives}(X, 'East'), \text{takes}(X, 'CS', 60) \]

Who takes a CS course?

\[ \text{takes}(X, 'CS', _) \]

<table>

e tc.
Summary of Backtracking

- Given a goal, Prolog tries rules in order of occurrence ("top-to-bottom"), using the first rule, the consequent of which matches the goal.

- If the rule has sub-goals, the sub-goals are satisfied in order of occurrence ("left-to-right"), resulting in bindings at each stage.

- If a goal sub-goal fails completely, Prolog retries to satisfy it using the next available option (e.g. the next rule).
Rule and Sub-Goal Ordering

Suppose the goal is \( \text{knows(john, Y, R)}. \)

This rule is tried first.

\[
\text{knows(X, Y, living)} :\neg \\
\text{lives(X, Z),} \\
\text{lives(Y, Z).}
\]

This sub-goal is satisfied first, which binds Z.

This sub-goal is satisfied next.

This rule is tried after the first rule is exhausted.

\[
\text{knows(X, Y, tutoring)} :\neg \\
\text{canTutor(Y, X).}
\]

In effect, we have disjunction (or) among rules, and conjunction (and) within rules. Remember that Prolog execution is depth-first search.
In AI, problem-solving trees are typically “And-Or” trees.
This applies to Prolog’s goals.

possible solution

conjunction of goals (within rule)

disjunction of goals (among rules)

conjunction

...
“Logical Variables” in Prolog

- A variable in Prolog is like an object that can have one of two states:
  - unbound
  - bound, to some Prolog term, e.g. an individual

- Once the variable is bound, it only gets re-bound in **backtracking**, which results in removing the former binding first.
Lists in Prolog

- Unlike Scheme lists, Prolog lists use square brackets and require comma separators:
  - [a, b, 123]
  - [[foo, bar], []]

- There is no explicit cons, first, rest. Rather unification is used for this purpose:
  - [First | Rest] = [1, 2, 3, 4]
    unifies with First ← 1, Rest ← [2, 3, 4]
  - [First | Rest] does not unify with []

Lists in Prolog

- Second, third, etc. are also not necessary:

  [First, Second, Third | More] = [1, 2, 3, 4, 5]

  unifies with:
  First ← 1, Second ← 2, Third ← 2,
  More ← [4, 5]
Movie Database (used in hw8)

- % movie([Title, Year], Director, Categories), e.g.
  
  movie(["Being John Malkovich", 1999], "Spike Jonze", [comedy, fantasy]).

- % actress(Name, [Birth City, State], Year), e.g.
  
  actress("Drew Barrymore", ['Culver City', 'California'], 1975).

- % actor(Name, [Birth City, State], Year), e.g.
  

- % plays(Player, Part, [Title, Year]), e.g.
  
  plays("Ben Affleck", 'Rafe', ['Pearl Harbor', 2001]).
Numeric Aspects

- Numbers can be compared like any other goal:
  - $2 < 3$ succeeds
  - $5 =< -5$ fails

- Numeric comparisons (caution):
  - $<$   $>$   $<=$   $=>$   $=$\ $=$::=$
Numeric Operators: Different!!

- 2+3 is not 5
  It is an unevaluated term, effectively +(2, 3)

- The 'is' operator causes evaluation:
  X is 2+3
  binds X to 5.
Numeric relations will also cause evaluation

- $2 < 3+4$ ok as a goal.
  - *is* is not needed here; Evaluation is forced.

- Most numeric functions are *not reversible* as regular goals are.
  - $5$ is $X+4$ *won't* solve for $X$ if it isn't bound.

- Arguments to arithmetic functions must be already bound.
Non-deterministic Programming

- One interpretation of “non-deterministic”:
  - Find all solutions by finding one solution.
  - Solutions can here be for the overall problem or a sub-problem.
Example of ND Programming

- member(X, [X | _]).
- member(X, [_ | L]) :- member(X, L).

- We think about this as either:
  - checking
  - generating
Generating vs. Testing

Consider:

\[\text{member}(X, [X | \_]).\]

\[\text{member}(X, [\_ | L]) :\text{member}(X, L).\]

This predicate can be viewed as a member tester.

It can also be viewed as a member generator.
## Generating vs. Testing

<table>
<thead>
<tr>
<th>test</th>
<th>generate</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>- member(3, [1, 2, 3, 4, 5]).</code></td>
<td><code>- member(X, [1, 2, 3, 4, 5]).</code></td>
</tr>
<tr>
<td>yes</td>
<td><code>X = 1 ;</code></td>
</tr>
<tr>
<td><code>- member(6, [1, 2, 3, 4, 5]).</code></td>
<td><code>X = 2 ;</code></td>
</tr>
<tr>
<td>no</td>
<td><code>X = 3 ;</code></td>
</tr>
<tr>
<td></td>
<td><code>X = 4 ;</code></td>
</tr>
<tr>
<td></td>
<td><code>X = 5 ;</code></td>
</tr>
<tr>
<td></td>
<td>no</td>
</tr>
</tbody>
</table>
Exercise

Extend member to have a 3rd argument: the residue left after the first element is removed from the list:

?- member(X, [1, 2, 3, 4], R).

X = 1,
R = [2, 3, 4] ;

X = 2,
R = [1, 3, 4] ;

X = 3,
R = [1, 2, 4] ;

X = 4,
R = [1, 2, 3] ;

No
Generating with `append`

**functional**

?- append ([1, 2, 3], [4, 5], Z).

Z = [1, 2, 3, 4, 5] ;

no

```prolog
append ([|], M, M).

append ([A | L], M, [A | N]) :-
    append (L, M, N).
```

**relational**

?- append (X, Y, [1, 2, 3, 4, 5])

X = [ ],
Y = [1, 2, 3, 4, 5] ;

X = [1],
Y = [2, 3, 4, 5] ;

X = [1, 2],
Y = [3, 4, 5] ;

...

X = [1, 2, 3, 4, 5],
Y = [ ] ;

no
Using a Generator as a "for" loop

?- for(I, 5, 8).
I = 5 ;
I = 6 ;
I = 7 ;
I = 8 ;
No

Definition:
for(M, M, N) :- M =< N.
for(I, M, N) :-
   M < N,
   M1 is M+1,
   for(I, M1, N).

Caution: Won't work in reverse, due to is.
Generating an Infinite Set

?- for(I, 5).
I = 5 ;
I = 6 ;
I = 7 ;
I = 8 ;

Definition:
for(M, M).
for(I, M) :-
    M1 is M+1,
    for(I, M1).

Caution: Won't work in reverse, due to is.
Exercise: Generate all Pairs in $N \times N$

?- pair(I, J).

I = 0
J = 0 ;

I = 0
J = 1 ;

I = 1
J = 0 ;

I = 0
J = 2 ;

I = 1
J = 1 ;
.
.
.
Example of ND Programming

- permutation(X, Y) is true if list Y is a permutation of list X.

- An attempt:
  permutation(X, Y) :- sort(X, Z), sort(Y, Z).

- This is logical, but doesn’t work; the built-in sort is uni-directional.

```
?- sort(X, [1, 2, 3]).
ERROR: sort/2: Arguments are not sufficiently instantiated
```

- [side issue: built-in sort also removes duplicates.]
Permutation

- permutation([], []).
- permutation(L, [A | M]) :-
  member(A, L, Residue),
  permutation(Residue, M).
  member(A, [A | X], X).
- member(A, [B | X], [B | Y]) :- member(A, X, Y).
slowsort (joke)

% slowsort(\(X, Y\)) is true when \(Y\) is a sorted permutation of \(X\).

slowsort(\(X, Y\)) :- permutation(\(X, Y\)), sorted(\(Y\)).

% sorted(\(Y\)) is true when \(Y\) is a list of elements in non-decreasing order

sorted([]).

sorted([\(_\)])

sorted([\(A, B | X\)]) :- A <= B, sorted([B | X]).
N-Queens Problem (NDP)

- Two queens on a chessboard are “attacking” if they are in a common row, column, or diagonal.

- Given a board size $N$, find a solution (or all solutions) for placing $N$ queens so that no two are attacking.
Example, $N = 4$

Possible state representation:

\[
\begin{bmatrix}
[1, 3], [2, 1], [3, 4], [4, 2]
\end{bmatrix}
\]
Example, Attacking
Solving Queens

- Given a list of columns and unoccupied rows:
  - If columns is empty, succeed.

  For the first column:
  - If there is a row where the queen is not being attacked, place it and recurse.

  If no such row, fail (backtrack).
queens(N, S) :-
    range(1, N, Range),
    solve(Range, Range, [], Solution),
    reverse(Solution, S).

% solve(Rows, Cols, Acc, Solution)

solve([], _, Acc, Acc).

solve([Col | Cols], Rows, Acc, Sol) :-
    member(Row, Rows, Residue),
    noAttack([Col, Row], Acc),
    solve(Cols, Residue, [[Col, Row] | Acc], Sol).
% noAttack([Col, Row], Pairs) succeeds if pair [Col], Row] does not
% attack the other Pairs, assuming
% the other Pairs don't attack each other.

noAttack(_, []). 
noAttack([Col1, Row1], [[Col2, Row2] | Pairs]) :-
    Col1 =\= Col2,
    Row1 =\= Row2,
    abs(Col1-Col2) =\= abs(Row1-Row2),
    noAttack([Col1, Row1], Pairs).
member(A, [A | X], X).
member(A, [B | X], [B | Y]) :- member(A, X, Y).

range(M, N, []) :- M > N.
range(M, N, [M | L]) :- M =< N, M1 is M+1, range(M1, N, L).

reverse(L, M) :- reverse(L, [], M).
reverse([], M, M).
reverse([A | L], M, R) :- reverse(L, [A | M], R).
The “42” Game
(homework problem)

Given:
- A set of positive integers: [2, 4, 5, 7]
- A set of reusable operators: [+,-,*]
- A target: 42

Construct an expression (as a syntax tree) showing how to make the target from the integers.

?- solve42([+, *, -], [2, 4, 5, 7], 42, Exp).
Exp = [*, [-, [*, 2, 5], 4], 7]
Approach to 42: Non-Deterministic Programming

- If there is only one integer in the set:
  - There is no choice. Either it is the same as the goal or not.

- Otherwise:
  - Split the integers into two non-empty subsets.
  - Compute a tree that could be constructed from each of the subsets.
  - Choose an operator for the root joining the two trees.
  - Check to see whether the overall tree meets the given target.
Strong recommendations

- Don’t evaluate a tree until the final tree is built.

- Don’t try to optimize by evaluating sub-trees during the solution search (at least not for this assignment).
Prolog has a built-in an infix operator precedence parser:

- $3+4*5$ is really:
  - $+(3, *(4, 5))$

How can you be sure? Try unifying:

?- 3+4*5 = +(3, *(4, 5)).

Yes
Evaluating an Expression

- The *is* operator will evaluate an expression. = (unification) will not:

  ?- X is 3+4*5.

  X = 23

  ?- X is +(3, *(4, 5)).

  X = 23

  ?- 23 = 3+4*5.

  No

  ?- X = +(3, *(4, 5)), Y is X.

  X = 3+4*5,
  Y = 23
Composing/Decomposing an Expression

- Infix operator =.. (called “univ”) will build an expression from an operator and arguments, or take an expression apart:

  ?- X =.. [+ , 3 , 4].  % compose

  X = 3+4

  ?- 3+4 =.. Y.  % decompose

  Y = [+ , 3 , 4]
Splitting a List

- Only concerned with lists of 2 or more elements (why?)

```prolog
?- split([1, 2, 3, 4], X, Y).

X = [1, 2, 3]
Y = [4] ;
  .
  .
  .
X = [1, 4]
Y = [2, 3]
```
Splitting a List

- The tricky part is making sure that you get every way of splitting.

- Ideally you get back each way of splitting only once.
Base Case

- A list of exactly two elements is easy to split.
How to split a list of > 2 elements

- Remove an element E from the list (using an extended 'member' predicate).
- Recursively split the remaining elements into two.
- Add E back to the first list.
- Exploit symmetry by using an auxiliary predicate and calling it twice from the interface predicate:
  - `split(X, L, R) :- split2(X, L, R).`
  - `split(X, L, R) :- split2(X, R, L).`
The solve42/4 predicate

- \texttt{solve42(Ops, Values, Result, Exp)} :- \ldots

- \textsc{Ops} is the set of operators.

- \textsc{Values} is the list of values to be combined.

- \textsc{Result} is the value of the expression, which will need to \texttt{unify} with the target if one is specified.

- \textsc{Exp} is the tree or expression itself.
42 Example (output in tree form)

?- setof(Exp, solve42([+, *], [1, 3, 4, 5], 42, Exp), Z).

Z = [ [*", [", 1, 5], [", 3, 4]]],
    [*", [", 1, 5], [", 4, 3]]],
    [*", [", 3, 4], [", 1, 5]]], ... 
]
Generator/Test Example: Map Coloring

A map
Map Coloring (2)

A map

Corresponding graph
Map Coloring (3)

Prolog Clause

\[
\text{map}([A, B, C, D, E, F, G]) :- \\
\text{next}(A, B), \\
\text{next}(A, C), \\
\text{next}(A, D), \\
\text{next}(A, E), \\
\text{next}(B, D), \\
\text{next}(B, F), \\
\text{next}(C, D), \\
\text{next}(C, E), \\
\text{next}(C, F), \\
\text{next}(D, F), \\
\text{next}(E, F), \\
\text{next}(E, G), \\
\text{next}(F, G). \\
\]

Graph
next(X, Y) :- color(X), color(Y), X \( \neq \) Y.

\[
\begin{align*}
\text{color(red).} \\
\text{color(blue).} \\
\text{...}
\end{align*}
\]

These and the preceding clause are the entire program.
Sudoku

- Sudoku is basically a graph-coloring problem.

- Adjacency is no longer binary. Any two squares in the same row, column, or sub-square are considered “adjacent”. 
Sudograph (pseudo-graph?)

- $G =$
  - List of Nodes (logical variables)
  - List of constraints
    - Each constraint is a list of variables
    - No two variables in the same constraint can have the same node values.
Sudograph setup

test(Nodes, Constraints, Colors):-
   Nodes = [A, B, C, D, E, F, G],
   Constraints = [[A, B, C],
                  [B, C, D],
                  [C, D, E],
                  [D, E, F],
                  [E, F, G],
                  [G, A, B]],
   Colors = [red, blue, green, yellow],
   sudographSolver(Nodes, Constraints, Colors).

?- test(Nodes, Constraints, Colors).
Colors: [red, blue, green, yellow]
Nodes:  [red, blue, green, red, blue, green, yellow]
Constraints:  
              [red, blue, green]
              [blue, green, red]
              [green, red, blue]
              [red, blue, green]
              [blue, green, yellow]
              [yellow, red, blue]
Solving “Logic” Puzzles

hmmm ...
The “Zebra” Problem
(aka “Einstein’s Riddle”?)

Five people of different nationalities, with different occupations, live in consecutive houses on a street. These houses are painted different colors. Each person has a different pet and a different favorite drink.

Given:

1. The English person lives in the red house.
2. The Spanish person owns a dog.
3. The green house is on the right side of the white house.
4. The Italian drinks tea.
5. The Norwegian lives in the first house on the left.
6. The photographer breeds snails.
7. The Norwegian’s house is next to the blue one.
8. The Japanese person is a painter.
9. The fox is in a house next to that of the physician.
10. The diplomat lives in the yellow house.
11. The owner of the green house drinks coffee.
12. The violinist drinks orange juice.
13. The horse is in a house next to that of the diplomat.
14. Milk is drunk in the middle house.

Determine: who owns the zebra?; who drinks water?
Analysis

- There are 5 “houses”, which can be represented as a parenthesized structure:
  - (Nationality, Colo, Occupation, Pet, Drink)

- There is a list of 5 houses:
  - $L = [_, _, _, _, _]$

- Note that order is important in the list (left-to-right).

- Each clue places a constraint on the list.

- The questions to be answered are:
  - Find $X$ where $\text{member}((X, _, _, \text{zebra}, _), L)$.
  - Find $Y$ where $\text{member}((Y, _, _, _, \text{water}), L)$. 
Translating Clues

1. The English person lives in the red house.
   
   clue1(L) :- nationality(english, H), color(red, H), house(H, L).

2. The Spanish person owns a dog.
   
   clue2(L) :- nationality(spanish, H), pet(dog, H), house(H, L).

3. The green house is on the right side of the white house.
   
   clue3(L) :- color(green, G), color(white, W), rightof(G, W, L).

Helpers:

   house(X, L) :- member(X, L).

   rightof(X, Y, L) :- leftof(Y, X, L).

   leftof(X, Y, [X, Y | _]). % assume “immediate” left of
   leftof(X, Y, [_ | L]) :- leftof(X, Y, L).
Unifying with House Structures

nationality( N, (N, _, _, _, _)).
color( C, (_, C, _, _, _)).
occupation( O, (_, _, O, _, _)).
pet( P, (_, _, _, P, _)).
drink( D, (_, _, _, _, D)).
Using the Clues Together:

clues(L) :-
    clue14(L), % strategic placement
    clue1(L),
    clue2(L),
    clue3(L),
    clue4(L),
    clue5(L),
    clue6(L),
    clue7(L),
    clue8(L),
    clue9(L),
    clue10(L),
    clue11(L),
    clue12(L),
    clue13(L),
    true.

solution(Z, W, L) :-
    clues(L),
    pet(zebra, H1), nationality(Z, H1), house(H1, L),
    drink(water, H2), nationality(W, H2), house(H2, L).
Tester, with Uniqueness Test  
(using if-then-else P \rightarrow Q; R)

```
test :-
solution(Z, W, L)
    -> (
        solution(_, _, M), L \=\= M
        -> write('The solution is not unique.'),
            write('One solution is: '), nl, pprint(L), nl,
            write('Another solution is: '), nl, pprint(M)
        ;
        write('The solution is unique: '), nl,
        pprint(L), nl,
        write('The '), write(Z), write(' owns the zebra.'), nl,
        write('The '), write(W), write(' drinks water.'), nl
    )

    ; write('There is no solution'), nl.
```
Quiz 3: Translate the rest of the clues.

1. The English person lives in the red house.
   clue1(L) :- nationality(english, H), color(red, H), house(H, L).

2. The Spanish person owns a dog.
   clue2(L) :- nationality(spanish, H), pet(dog, H), house(H, L).

3. The green house is on the right side of the white house.
   clue3(L) :- color(green, G), color(white, W), rightof(G, W, L).

4. The Italian drinks tea.
5. The Norwegian lives in the first house on the left.
6. The photographer breeds snails.
7. The Norwegian’s house is next to the blue one.
8. The Japanese person is a painter.
9. The fox is in a house next to that of the physician.
10. The diplomat lives in the yellow house.
11. The owner of the green house drinks coffee.
12. The violinist drinks orange juice.
13. The horse is in a house next to that of the diplomat.
14. Milk is drunk in the middle house.
More on Predicate Logic:

Quantifiers
In addition to truth function operators of proposition logic, predicate logic introduces **quantifiers** for expressing variation over individuals:

- $(\forall x) p(x) : \text{for all } x, p(x)$ - **universal quantifier**

- $(\exists x) p(x) : \text{for some } x, p(x)$ - **existential quantifier**
Order of Quantifiers

- $(\forall x) (\exists y) \text{ knows}(x, y)$:
  Everyone knows someone.

- $(\exists x) (\forall y) \text{ knows}(x, y)$:
  Someone knows everyone.

- $(\exists x) (\forall y) \neg \text{ knows}(x, y)$
  Someone knows no one.

- $(\exists x) (\exists y) \text{ knows}(x, y) \land x \neq y$
  Someone knows someone other than him/herself.
Quantifiers in Prolog

- In most formulas, quantifiers are implicit:
  - If a variable appears in the head, it is for-all quantified in the rule.
  - If a variable appears in the body, but not in the head, it is there-exists quantified.

- Examples:
  - p(X, Y) :- q(X), r(X, Y) says:
    \[(\forall x) (\forall y) [if (q(x) and r(X, Y)) then p(X, Y)].\]
  - p(X) :- q(X), r(X, Y) says:
    \[(\forall x) [if (\exists y) (q(x) and r(X, Y)) then p(X)].\]
Quantifiers in Prolog

- The $\exists$ can be made explicit:

Examples:
- $p(X) :- q(X), r(X, Y)$ says:
  $(\forall x) [\text{if } (\exists y) (q(x) \text{ and } r(X, Y)) \text{ then } p(X)].$
- $p(X) :- Y^{q(X), r(X, Y)}$ says the same thing.
- $^\exists$ is an “infix” version of $\exists$. 
Where it Really Matters: setof

- Consider
  - setof(X, p(X, Y), Z).

- How is Y quantified? If you want it to be $\exists$, the usual case, use:
  \[
  \text{setof}(X, Y \^ p(X, Y), Z).
  \]

- If you leave it off, it is a free variable, and may become bound in solving, in which case all other solutions would use the same Y.

- You won’t get all solutions for all Y in this case.

- Typical use of the unquantified version:
  - r(X, Z) :- setof(X, p(X, Y), Z).
  - Here there is a set of Z for each possible X.
The variable _ is special.

It is called a “throw-away” or “don’t care” variable.

_ unifies with anything, but different instances of _ within the same clause are not unified, unlike other variables.
A variable that occurs only once in a clause is called a "singleton variable".

Often singleton variables are the result of a typing error, and certain compilers will warn about them.

To prevent the warning, when this is the intention, use a variable that begins with __, such as __Name rather than Name.
== in Prolog is not unification

- == is literal equality
- a == a succeeds
- a == b fails
- X == a fails if X is unbound (unlike =)
- X = a, X == a succeeds (X becomes bound)
- X == Y fails if either is unbound
Equality vs. Unifiability

- `\==` is literal inequality:
  - `a \== a` fails
  - `a \== b` succeeds
  - `X \== Y` succeeds if either `X` or `Y` is unbound

- `\=` is the not-unifiable operator:
  - `X \= Y` is same as `\+ (X = Y)`
  - `X \= Y` fails if either `X` or `Y` is unbound
  - `a \= b` succeeds
Other comparison operators

- @< compare arbitrary terms (e.g. lists)
- @> in lexicographic order
- @=<
- @>=
Some Reversible Arithmetic can be Simulated with Lists

Number N is represented as a list of N 1's

\[ \text{sum}([\ ], Y, Y). \]
\[ \text{sum}([1 \mid X], Y, [1 \mid Z]) :- \text{sum}(X, Y, Z). \]

The following doesn’t quite work for all inverses. A problem arises in factoring 0.

\[ \text{prod}([\ ], Y, []). \]
\[ \text{prod}([1 \mid X], Y, Z) :- \text{prod}(X, Y, Z_1), \]
\[ \quad \text{sum}(Z_1, Y, Z). \]

<table>
<thead>
<tr>
<th>?- \text{sum}([1,1,1], [1,1], Z).</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ Z = [1,1,1,1,1] ]</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>?- \text{sum}(X, Y, [1,1,1,1,1]).</th>
</tr>
</thead>
</table>
| \[ X = [], \]
| \[ Y = [1,1,1,1,1] ; \]
| \[ X = [1], \]
| \[ Y = [1,1,1,1,1] ; \]
| \[ X = [1,1], \]
| \[ Y = [1,1,1] ; \]
| \[ X = [1,1,1], \]
| \[ Y = [1,1] ; \]
| \[ X = [1,1,1,1,1], \]
| \[ Y = [] ; \]

no
Example: Towers of Hanoi

Move only one disk at a time.
Never place a larger disk on a smaller one.
Solving Towers of Hanoi

Some approaches:

- Pre-programmed solution
  - Recursive solution is easy in most languages

- Let prolog find solution using depth-first search
  - Trickier, but shows off Prolog’s capabilities
  - May not find shortest solution

- Program breadth-first search in Prolog
  - Still trickier

- Program iterative-deepening search
  - Easier than breadth-first
To move N disks from stack From to stack To:
To move N disks from stack *From* to stack *To*:

- Move N-1 disks from stack *From* to stack *Other* (the stack other than *From* and *To*)

A key point throughout is that the N-1 disk moves can be done without violating the constraint that a larger disk not be put atop a smaller one.
To move N disks from stack **From** to stack **To**:

- Move N-1 disks from stack **From** to stack **Other** (the stack other than **From** and **To**)
- Move 1 disk from stack **From** to stack **To**
To move N disks from stack \textit{From} to stack \textit{To}:

- Move N-1 disks from stack \textit{From} to stack \textit{Other} (the stack other than \textit{From} and \textit{To})
- Move 1 disk from stack \textit{From} to stack \textit{To}
- Move N-1 disks from stack \textit{Other} to stack \textit{To}
Data Representation

- Number the disks 1, 2, 3, ... smallest to largest.
- Use numeric value to detect size constraint.
Pre-Programmed Towers of Hanoi(5)

% towers(N, From, To, Moves) means that Moves is the list of % moves to move N disks from stack From to stack To

towers(N, From, To, Moves) :-
    towers(N, From, To, [ ], ReversedMoves),
    reverse(ReversedMoves, Moves).

% towers(N, From, To, Acc, Moves) means that Moves is the reverse of the % of moves to move N disks from stack From to stack To, with % Acc being the reverse of the accumulated moves going in (to avoid append)

% towers(N, From, To, Acc, Moves).

towers(0, _, _, Acc, Acc).

towers(N, From, To, Acc, Moves) :-
    other(From, To, Other),
    N1 is N - 1,
    towers(N1, From, Other, Acc, Moves1),
    towers(N1, Other, To, [ [From, To] | Moves1], Moves).

other(1, 2, 3).
other(1, 3, 2).
other(2, 1, 3).
other(2, 3, 1).
other(3, 1, 2).
other(3, 2, 1).
Depth-First Towers of Hanoi
Depth-First Towers of Hanoi (1)
Does not require a human to solve the puzzle first

First characterize the possible moves.

This is a move from stack 1 to stack 2:

\[
\begin{align*}
\text{from / to} & \quad \text{stack 1 before} & \quad \text{stack 2 after} \\
\text{move([1, 2], [[F1 \mid R1], S2, S3], [R1, [F1 \mid S2], S3]):=} & \quad \text{ok(F1, S2).} \\
& \quad \text{provided that it is ok to move disk F1 onto stack S2}
\end{align*}
\]
Depth-First Towers of Hanoi (2)

All the possible moves in six rules:

\[
\begin{align*}
\text{move}([1, 2], [[F1 \mid R1], S2, S3], [R1, [F1 \mid S2], S3]) & : - \text{ ok}(F1, S2). \\
\text{move}([1, 3], [[F1 \mid R1], S2, S3], [R1, S2, [F1 \mid S3]]) & : - \text{ ok}(F1, S3). \\
\text{move}([2, 1], [S1, [F2 \mid R2], S3], [[F2 \mid S1], R2, S3]) & : - \text{ ok}(F2, S1). \\
\text{move}([2, 3], [S1, [F2 \mid R2], S3], [S1, R2, [F2 \mid S3]]) & : - \text{ ok}(F2, S3). \\
\text{move}([3, 1], [S1, S2, [F3 \mid R3]], [[F3 \mid S1], S2, R3]) & : - \text{ ok}(F3, S1). \\
\text{move}([3, 2], [S1, S2, [F3 \mid R3]], [S1, [F3 \mid S2], R3]) & : - \text{ ok}(F3, S2).
\end{align*}
\]

\text{from} / \text{to} \quad \text{state before} \quad \text{state after} \quad \text{condition}
When is it ok to move a disk onto a stack? Assume the disks are represented by numbers 1, 2, 3, ... with smaller numbers representing smaller disks.

ok(_, []).                           \hspace{1.5in} \text{empty target stack}

ok(A, [B | _]) :- smaller(A, B).

smaller(A, B) :- A < B.
towers([S1, S2, S3], Moves) will mean that Moves is a valid move sequence that results in S1 and S2 being empty (so all disks are on S3).

towers([S1, S2, S3], Seen, Moves) means the same, except that Seen will be a list of all previous states (to prevent infinite looping).

towers(InitialState, Moves) :- towers(InitialState, [], Moves).

towers([[ ], [ ], [ ]], [], []). % final state, no more moves

towers(Before, Seen, [Move | Moves]) :-
nonMember(Before, Seen),
move(Move, Before, After),
towers(After, [Before | Seen], Moves).
Depth-First Towers of Hanoi (5)

Auxiliary Predicates:

\[
\text{nonMember}(X, L) :- \neg \text{member}(X, L). \\
\text{member}(X, [X \mid \_]). \\
\text{member}(X, [\_ \mid L]) :- \text{member}(X, L).
\]
Reverse the pegs by moving peg “forward” or jumping forward over a peg of either color.

Work out a depth-first solution in Prolog.

(You don’t have to check for cycles, because there can’t be any.)
Difference Lists

- The standard append concatenates two lists in time proportional to the length of the first list.

- Is this the best we can do?
Difference Lists

- Is this the best we can do?

- Represent a list by a pair

\[ d(B, T) \]

where \( B \) ("body") looks a lot like a conventional Prolog list, but ends with variable \( T \) ("tail") instead of \([],\).

- Example:

\[ d([a, b, c | T], T) \]
Difference to Regular

- To convert a difference list to a regular list, simply unify the tail with []:
  - \(\text{d2r}(\text{d}(B, []), B)\).

- To convert a regular list to a difference list:
  - \(\text{r2d}([], \text{d}(T, T))\).
  - \(\text{r2d}([A | X], \text{d}([A | B], T)) :- \text{r2d}(X, \text{d}(B, T))\).

?- \text{r2d}([1,2,3], X).
X = \text{d}([1, 2, 3|_G261], _G261)
Appending Difference Lists

\[ d([a, b, c \mid T1], T1) \]

\[ d([e, f, g, h \mid T2], T2) \]

Unify \( T1 \) with the body of the second list to get

\[ d([a, b, c, d, e, f, g, h \mid T2], T2) \]

Variable \( T1 \) becomes bound. \( T2 \) is left unbound.
Appending Difference Lists

dappend(d(B1, T1), d(B2, T2), d(B1, T2)) :- T1 = B1.

Or more simply, since B1, etc. are just variables:

dappend(d(B1, B2), d(B2, T2), d(B1, T2)).

?- dappend(d([1,2,3 | T1], T1), d([4,5,6,7 | T2], T2), Z).

T1 = [4, 5, 6, 7 | T2],
Z = d([1, 2, 3, 4, 5, 6, 7 | T2], T2)
One Issue with Difference Lists

- The body of a difference list cannot be shared.

- However, the entire difference list as a term can be shared arbitrarily. When it gets used, copying may result.

- Thus the “win” with difference lists is in the case where sharing is not expected.
Prolog started life as a language for translating languages. The syntax was then changed to be more logic-like.

Grammar rules were re-introduced as “definite clause grammar” (DCGs).

Grammar parsing is based on difference lists of tokens “underneath”.
DCG (Definite Clause Grammar)

Example: Consider the following grammar for S-expressions:

- $S \rightarrow A$
- $S \rightarrow '(' T ')'$
- $T \rightarrow \varepsilon$ (where $\varepsilon$ is the empty string)
- $T \rightarrow S \ T$ (Essentially $T \rightarrow S^*$)
Translation to Prolog DCG

- Example: Consider the following grammar for S-expressions:
  - $S \rightarrow A$
  - $S \rightarrow (' T ')$
  - $T \rightarrow \varepsilon$ (where $\varepsilon$ is the empty string)
  - $T \rightarrow S \, T$ (Essentially $T \rightarrow S^*$)
  - $A \rightarrow 0 \mid 1$

- Non-terminals become predicate symbols (lower-case start).
- Literals (terminals) appear as list elements [...].
- Juxtaposition on the right becomes comma-separation.
  - $s \rightarrow a$.
  - $s \rightarrow ['(', t, ']')$.
  - $t \rightarrow []$.
  - $t \rightarrow s, t$.
  - $a \rightarrow [0] \mid [1]$. 
Parsing with DCGs

- The input is assumed to be a list of tokens.
- There is a built-in predicate 'phrase':
  
  \[
  \text{phrase(StartSymbol, TokenList)}.\]

- Suppose the conceptual input is
  
  \[
  (0())\]
  
  a valid S-expression.

- As a token-list, this would be:
  
  \[
  ['(', 0, '(', ')', ')']\]

?- phrase(s, ['(', 0, '(', ')', ')', ')']).

Yes
Parsing with DCGs

- An invalid S-expression:
  \[(0 ()\]

?- phrase(s, [('(', 0, ')'), (')')]).

No
Reversible Parsing

- By leaving the token list as a variable, Prolog will generate strings in the language.

- We may need to specify the length in advance, or depth-first search may cause infinite recursion.

```prolog
?- length(X, 3).
X = [_G235, _G238, _G241]
?- length(X, 3), phrase(s, X).
X = [', 0, ']
?- length(X, 0), phrase(s, X).
No
```
Example

Generate all strings of length 0 to 6, inclusive:

?- for(I, 0, 6), length(X, I), phrase(s, X).

I = 1, X = [0] ;

I = 1, X = [1] ;

I = 2, X = ['(', ')'] ;

I = 3, X = ['(', 0, ')'] ;

I = 6, X = ['(', 1, 1, '(')')', ')']

Yes
Using DCG’s for Semantics

- Syntax = Structure
- Semantics = Meaning

- Example: Arithmetic with variables (juxtaposition = multiply)

s --> t. % sum
s --> t, [+], s.

\( t \rightarrow f. \) % term
\( t \rightarrow f, t. \)

\( f \rightarrow v. \) % factor
\( v \rightarrow ['x'] \mid ['y'] \mid ['z']. \) % variable

?- phrase(s, [x, y, +, z, x]).
Yes
One Semantics: Parse Tree

s(T) --> t(T).
% sum

s(+(T, S)) --> t(T), [+], s(S).
% tree constructor, root +

t(F) --> f(F).
% term

t(*(F, T)) --> f(F), t(T).
% tree constructor, root *

f(T) --> v(T).
% factor

f(T) --> ['(', s(T), ')'].
% parenthesized sum

v(V) --> [V], {member(V, [x, y, z])}.
% variable

% { . . . } means to call ordinary goal in Prolog
Parse Examples

?- phrase(s(T), [x, +, y, +, z]).
T = x+ (y+z)

?- phrase(s(T), [x, y]).
T = x*y

?- phrase(s(T), [x, y, z]).
T = x* (y*z)

?- phrase(s(T), [x, +, y, z]).
T = x+y*z

?- phrase(s(T), [', x, +, y, '), z]).
T = (x+y)*z

?- phrase(s(T), [x]).
T = x
Alternate Semantics: Evaluation, in an Environment

env([[x, 3], [y, 5], [z, 7]]). % environment

s(S) --> t(S). % sum

s(S) --> t(X), [+], s(Y), {S is X + Y}.

t(F) --> f(F). % term

t(P) --> f(X), t(Y), {P is X*Y}.

f(S) --> v(S). % factor

f(S) --> ['('], s(S), [')']. % parenthesized sum

v(X) --> [V], {env(E), member([V, X], E)}. % variable
Evaluation Examples

?- phrase(s(X), [x]).
X = 3

?- phrase(s(X), [x, +, z]).
X = 10

?- phrase(s(X), [x, +, z, y]).
X = 38

?- phrase(s(X), ['(', x, +, z, ')', y]).
X = 50
A Third Semantics: Code Generation

- Say we want to generate code for a stack machine, with instructions:
  - push(Value)
  - add
  - multiply

- The value is left atop the stack.
- The code will be generated as a Prolog list.
Grammar with Code Generation

env([[x, 3], [y, 5], [z, 7]]). % environment

s(S) --> t(S). % sum
s(S) --> t(X), [+], s(Y), {append([X, Y, [add]], S)}. 

f(F) --> f(F). % term

f(S) --> v(S). % factor
f(S) --> ['(', s(S), ')']. % parenthesized sum

v([push(X)]) --> [V], {env(E), member([V, X], E)}. % variable

append/2 appends elements of a list of lists together.
Code Generation Examples

?- phrase(s(S), [x]).
S = [push(3)]

?- phrase(s(S), [y, z]).
S = [push(5), push(7), multiply]

?- phrase(s(S), [y, z, x]).
S = [push(5), push(7), push(3), multiply, multiply]

?- phrase(s(S), [y, +, z]).
S = [push(5), push(7), add]

?- phrase(s(S), [y, z, +, x, z]).
S = [push(5), push(7), multiply, push(3), push(7), multiply, add]
Exercise

- Write the code that simulates the stack machine.

- Repertoire:
  - push(Value)
  - add
  - multiply
How Grammar Rules are Represented Underneath

- A grammar rule with no argument is written as a Prolog clause with two arguments. These correspond to the body and tail of a difference list.
  - `a --> b, c.`

- Compiles into:
  - `a(B1, T2) :- b(B1, T1), c(T1, T2).`
The phrase Predicate

- phrase(Symbol, Sequence) :-
  Term =.. [Symbol, Sequence, []],
  call(Term). % call constructed term as a goal

- Example:
  - a --> b, c.

  phrase(a, Sequence) is equivalent to:

  a(Sequence, []).

- Recall:
  - a(B1, T2) :- b(B1, T1), c(T1, T2).
How Grammar Rules are Represented Underneath

- A grammar rule with an argument just adds another argument to the head:
  - \( a(X) \rightarrow b(X), c(X) \).

- Compiles into:
  - \( a(X, B1, T2) :\!-\! b(X, B1, T1), c(X, T1, T2) \).

- This simply adds more arguments to the constructed Term.
How Grammar Rules are Represented Underneath

- A grammar rule with a Prolog condition just adds that condition to the clause:
  - \( a(X) \rightarrow b(X), c(X), \{p(X)\} \).

- Compiles into:
  - \( a(X, B1, T2) :- b(X, B1, T1), c(X, T1, T2), p(X). \)
How Grammar Rules are Represented Underneath

- A grammar rule with terminals adds constants to the front of difference lists.
  - $a(X) \rightarrow [b], c(X)$.

- Compiles into:
  - $a(X, [b \mid B1], T1) :- c(X, B1, T1)$. 

Summary of DCG Syntax

- --> indicates a production.
- | may be used on the RHSs for **disjunction**.
- Terms not included in [...] or in {...} represent non-terminals in the grammar.
- Terms in [...] represent terminals. They can be variables or literals. More than one means to match each consecutively in the input.
- Terms in {...} are Prolog goals as is. They may share variables with the non-terminals.
- Non-terminals can have arguments.
Prolog Perspective

- A complete programming language

- Not a complete logic language
  - Restricted to “Horn Clauses”
  - Restricted form of negation
  - Quantifiers not completely general
  - Built-in arithmetic not reversible

- More powerful logic systems exist, e.g.
  - Otter/Planner9 (see CS 81)
Contemporary Extensions of Prolog

- Constraint logic programming
- Inductive logic programming
- Lambda-prolog
- Goedel
- Parallel prologs
- Prolog++
- ... (The list is quite long.)
