Proving Programs by Structural Induction

Robert Keller
February 2011
Verification Patterns

- **Structural induction on program structure** involves proving properties based on the manner in which programs are composed (e.g. Hoare logic).

- **Transition induction** involves proving properties based on the number of *steps executed* (e.g. Floyd assertions).

- **Structural induction on data** involves proving properties based on the definition of data types involved.
This is the “original” structural induction.

It is expressed most easily for functional programs.

However, we can transform any (sequential) program into a functional program (using McCarthy’s transformation).

So little generality, if any, is lost.
The idea is a generalization of mathematical induction:

If our only data type were the natural numbers, we know how to prove properties $P$ for all such numbers:

$$
\begin{align*}
& \frac{P(0) \quad P(n) \rightarrow P(n+1)}{(\forall n) \ P(n)}
\end{align*}
$$
Structural Induction on Lists

- \( P([ ]) \)  \( P(L) \rightarrow P([A | L]) \)  \((\forall L) P(L)\)

Here
- \([ ]\) is the empty list
- \(L\) represents an arbitrary list
- \(A\) is an arbitrary element of a list
Define (using rex):

\[\text{reverse}([\ ])) = [\ ];\]
\[\text{reverse}([A \mid L]) \Rightarrow \text{append}(\text{reverse}(L), [A]);\]

Show

\[(\forall L) \text{length}(\text{reverse}(L)) = \text{length}(L)\]

using

\[\text{length}([ \ ]) \Rightarrow 0;\]
\[\text{length}([A \mid L]) \Rightarrow 1+\text{length}(L);\]
Lemma

- \((\forall L)\) \(\text{length}(\text{append}(L, [A])) = 1 + \text{length}(L)\)

The definition of append is:

\[
\begin{align*}
\text{append}([], M) &= M; \\
\text{append}([A \mid L], M) &= [A \mid \text{append}(L, M)]
\end{align*}
\]

We’d show the lemma by induction too.
Proof of Example 0

- **Basis:** \( \text{length} (\text{reverse}([[]])) = \text{length}([]) \)
  
  Proof: \( \text{reverse}([]) = [] \), so by substitution
  
  \[ \text{length} (\text{reverse}([])) = \text{length}([]) \]

- **Induction step:**
  
  Assume \( \text{length} (\text{reverse}(L)) = \text{length}(L) \).
  
  Show \( \text{length} (\text{reverse}([A \mid L])) = \text{length}([A \mid L]) \).

But \( \text{reverse}([A \mid L]) = \text{append}(\text{reverse}(L), [A]) \)

so \( \text{length} (\text{reverse}([A \mid L])) = 1 + \text{length} (\text{reverse}(L)) \)

\( = 1 + \text{length}(L) \) [by induction hypothesis] \( = \text{length}([A \mid L]) \).
Example 1

- Define (using rex):
  \[
  \text{reverse}(L) = \text{reverse2}(L, [ ]); \\
  \text{reverse2}([ ], M) \Rightarrow M; \\
  \text{reverse2}([A | L], M) \Rightarrow \text{reverse2}(L, [A | M]);
  \]

- Show
  \[(\forall L) \text{ length(reverse(L)) = length(L)}\]

- Using
  \[
  \text{length}([ ]) \Rightarrow 0; \\
  \text{length}([A | L]) \Rightarrow 1+\text{length}(L);
  \]
Example 1

- Here $P(L)$ is $\text{length}(\text{reverse}(L)) = \text{length}(L)$

- Structural Induction says it \textit{suffices} to show:
  - $P([])$: $\text{length}(\text{reverse}([])) = \text{length}([])$
  - $P(L) \rightarrow P([A \mid L])$:
    - $\text{length}(\text{reverse}(L)) = \text{length}(L)$
    - $\rightarrow \text{length}(\text{reverse}([A \mid L])) = \text{length}([A \mid L])$
Example 1

- Structural Induction says it **suffices** to show:
  - $P([])$: $\text{length}(\text{reverse}([])) = \text{length}([])$
  - $P(L) \rightarrow P([A | L])$:
    - $\text{length}(\text{reverse}(L)) = \text{length}(L)$
    - $\rightarrow \text{length}(\text{reverse}([A | L])) = \text{length}([A | L])$

- Unfortunately, it will **not** be easy to show this directly, because the inductive part of the definition is **not** based on $\text{reverse}$, it is based on $\text{reverse2}$. 
Example 1

- So we have to **broaden** the $P$ we are showing to $P'$:
  - $P'(L)$:
    $$(\forall M) \ \text{length}(\text{reverse2}(L, M)) = \text{length}(L) + \text{length}(M)$$

- Then specialize to $M = []$
  
  $$\text{reverse}(L) = \text{reverse2}(L,[]) \ \text{and}$$
  $$\text{length}([]) = 0$$
  $$\text{length}(L) + 0 = \text{length}(L)$$

  we get the desired $P(L)$:
  $$\text{length}(\text{reverse}(L)) = \text{reverse}(L).$$
This broadening requirement is a typical phenomenon in verifying programs.

It occurs in most induction patterns in some form.

In some cases it requires creativity.
Example 1: Proof of $P'$

- Structural Induction says it **suffices** to show:
  - $P'([])$:
    $$(\forall M) \text{ length}(\text{reverse2}([], M)) = \text{length}([]) + \text{length}(M)$$
  - $P'(L) \rightarrow P'([A \mid L])$:  
    $$(\forall M) \text{ length}(\text{reverse2}(L, M)) = \text{length}(L) + \text{length}(M)$$
    $$\rightarrow \text{length}(\text{reverse2}([A \mid L], M)) = \text{length}([A \mid L]) + \text{length}(M)$$

- These two parts can be shown separately, as is the case with most inductive proofs.
Example 1: Proof of P' ': Basis

- Showing the basis:
  - $P'(\text{[]})$:
    \[(\forall M) \text{length}(\text{reverse2}([\text{}], M)) = \text{length}([\text{}]) + \text{length}(M)\]

- We use **symbolic evaluation**: $\text{reverse2}([\text{}], M) = M$
  from the definition of $\text{reverse2}$, and $\text{length}([\text{}]) = 0$.

- We have reduced the basis to:
  \[(\forall M) \text{length}(M) = 0 + \text{length}(M)\]
  and we can appeal to the definition of $+$ to verify this equality.
Example 1: Proof of $P'$: Induction Step

- Showing the induction step:
  - $P'(L) \rightarrow P'(A \mid L)$:
    
    $$(\forall M) \text{length}(\text{reverse2}(L, M)) = \text{length}(L) + \text{length}(M)$$
    
    $\rightarrow (\forall N) \text{length}(\text{reverse2}([A \mid L], N)) = \text{length}([A \mid L]) + \text{length}(N)$$

- (We use different quantifiers $M$ and $N$ to avoid messing up later.)

- Assume the stmt before the $\rightarrow$, to show the stmt after.
Example 1: Proof of P': Induction Step

- Assume \((\forall M)\) \(\text{length}(\text{reverse2}(L, M)) = \text{length}(L) + \text{length}(M)\) to show:
  \((\forall N)\) \(\text{length}(\text{reverse2}([A \mid L], N)) = \text{length}([A \mid L]) + \text{length}(N)\)

- Again evaluate symbolically:
  \(\text{reverse2}([A \mid L], N) = \text{reverse2}(L, [A \mid N])\)

Now we can view \([A \mid N]\) as \(M\) in the assumed equality, so
\(\text{length}(\text{reverse2}(L, [A \mid N])) = \text{length}(L) + \text{length}([A \mid N])\)
\[= \text{length}(L) + 1 + \text{length}(N)\quad \text{(LHS)}\]

Also, the rhs of the “to show” is \(\text{length}([A \mid L]) + \text{length}(N)\)
\[= 1 + \text{length}(L) + \text{length}(N)\quad \text{(RHS)}\]

- Allowing ourselves the commutative law for + then gives the equality to be shown.
While we did not use a totally formal system to the derivation, we could have.

What we did was a little more formal than “…” type of reasoning (“elliptic reasoning”).
Structural Induction in Jape

- Load functional_programming theory
- “Proof by clicking” (and **double-clicking** does evaluation/auto-expansion)
- Rules:

  ```
  = reflexive (A=A)
  = transitive (A=B AND B=C ⇒ A=C)
  = symmetric (A=B ⇒ B=A)
  A=C AND B=D ⇒ (A,B)=(C,D)
  F x = G x ⇒ F = G
  F (x,y) = G (x, y) ⇒ F = G
  ```

  rewrite
  rewrite backwards
  Unfold/Fold with hypothesis
  Unfold with hypothesis
  Fold with hypothesis

  Find
  Flatten

  List Induction
  Boolean cases
  Monoid Definition

  i.e. structural induction
Notation

- \([\ ]\) is the empty list
- \([a]\) is the list of one element, \(a\)
- ++ is list concatenation or append
- \(\circ\) is function composition:
  \[(f \circ g)x = f(g(x))\]
The list induction model Jape uses is different from the typical asymmetric one using ‘cons’ i.e. [ | ] in rex.

The definition is:
- [] is a list (the empty list).
- [a] is a list (the list of one element, a).
- If x and y are lists, then so is x++y (the concatenation, or appending, of x followed by y).
Structural Induction in the Jape Model

- To prove a property $P$ for all lists, prove:
  - $P([])$.
  - $P([a])$, for any single-element list.
  - If $P(x)$ and $P(y)$, then $P(x++y)$.

  - So there are two base cases.

  - There are two parts to the induction hypothesis.
The reverse of the reverse of a list is the original list itself:

- $\text{rev} \circ \text{rev} = \text{id}$

- recalling that $\circ$ is functional composition
Definition of rev

- \( \text{rev} \ [\ ] = [\ ] \)
- \( \text{rev} \ [a] = [a] \)
- \( \text{rev} \ (x ++ y) = (\text{rev} \ y) ++ (\text{rev} \ x) \)
Steps (working backward)

- Introduce a variable representing the argument list:
Steps (working backward)

- Text select both arguments and indicate list induction:
Steps (working backward)

- Prove the [] base case by several double-clicks (which search for applicable rules).

```
1: [] = []                  = reflexive
2: [] = id[]                Fold id 1
3: rev([]) = id[]           Fold rev'0 2
4: rev(rev([])) = id[]      Fold rev'0 3
5: (rev · rev)[] = id[]     Fold · 4
...
6: (rev · rev)[x3] = id[x3] = assumption
7: (rev · rev)xs = id xs    assumption
8: (rev · rev)ys = id ys
   ...                       
9: (rev · rev)(xs + ys) = id(xs + ys)
10: (rev · rev)x = id x     listinduction 5,6,7–9
11: rev · rev = id          ext 10
```

"Fold" rule means to replace function app with corresponding definition, working backward.

[] base case done
Steps (working backward)

- Prove the [x] base case by several double-clicks (which search for applicable rules).

```
1: [] = []
2: [] = id[]
3: rev([]) = id[]
4: rev(rev([])) = id[]
5: (rev • rev)[] = id[]
6: [x3] = [x3]
7: [x3] = id[x3]
8: rev([x3]) = id[x3]
9: rev(rev[x3]) = id[x3]
10: (rev • rev)[x3] = id[x3]
11: (rev • rev)x = id x
12: (rev • rev)y = id y
...  
13: (rev • rev)(xs ++ ys) = id(xs ++ ys)
14: (rev • rev)x = id x
15: rev • rev = id
```

[x] base case done

“Fold” rule means to replace function app with corresponding definition, working backward.
Steps (working backward)

- Prove the induction step. The first few steps can be done automatically.

```
11: (rev ∙ rev)xs = id xs, (rev ∙ rev)ys = id ys  \text{assumptions}
\ldots
12: \boxed{\text{rev}(\text{rev } xs) ++ \text{rev}(\text{rev } ys) = xs ++ ys}
13: \text{rev}(\text{rev } xs) ++ \text{rev}(\text{rev } ys) = \text{id}(xs ++ ys)
14: \text{rev}(\text{rev } ys) ++ \text{rev } xs = \text{id}(xs ++ ys)
15: \text{rev}(\text{rev}(xs ++ ys)) = \text{id}(xs ++ ys)
16: (rev ∙ rev)(xs ++ ys) = \text{id}(xs ++ ys)
17: (rev ∙ rev)x = \text{id } x  \text{listinduction 5,10,11–16}
18: rev ∙ rev = \text{id}  \text{ext 17}
```
Steps (working backward)

- From here on, we need to be more explicit, apparently:

```
6: [x3]=[x3]
7: [x3]=id[x3]
8: rev([x3])=id[x3]
9: rev(rev([x3]))=id[x3]
10: (rev ∘ rev)[x3]=id[x3]
11: (rev ∘ rev)x=id xs, (rev ∘ rev)ys=id ys
    ...
12: rev(rev xs)++rev(rev ys)=xs++ys
13: rev(rev xs)++rev(rev ys)=id(xs++ys)
14: rev(rev ys++rev xs)=id(xs++ys)
15: rev(rev(xs++ys))=id(xs++ys)
16: (rev ∘ rev)(xs++ys)=id(xs++ys)
17: (rev ∘ rev)x=id x
18: rev ∘ rev=id
```
Steps (working backward)

- More explicit steps

6: \([x3]=[x3]\)
7: \([x3]=\text{id}[x3]\)
8: \(\text{rev}(x3)=\text{id}[x3]\)
9: \(\text{rev}(\text{rev}(x3))=\text{id}[x3]\)
10: \((\text{rev} \cdot \text{rev})[x3]=\text{id}[x3]\)
11: \((\text{rev} \cdot \text{rev})x3=\text{id} x3\)
12: \((\text{rev} \cdot \text{rev})ys=\text{id} ys\)
13: \(\text{rev}(\text{rev} x3)++(\text{rev} \cdot \text{rev})ys=\text{id} x3+ysi\)
14: \(\text{rev}(\text{rev} x3)++(\text{rev} \cdot \text{rev})ys=\text{id} x3+ysi\)
15: \(\text{rev}(\text{rev} x3)++(\text{rev} \cdot \text{rev})ys=\text{id} x3+ysi\)
16: \(\text{rev}(\text{rev} x3)++(\text{rev} \cdot \text{rev})ys=\text{id} x3+ysi\)
17: \(\text{rev}(\text{rev} x3)++(\text{rev} \cdot \text{rev})ys=\text{id} x3+ysi\)
18: \(\text{rev}(\text{rev} x3)++(\text{rev} x3)=\text{id}(x3+ysi)\)
Steps (working backward)

- Obviously we are on the right track. How to close?

</table>

14: \text{rev}(\text{rev} \; x) = x  
15: \text{rev}(\text{rev} \; x) = \text{id} \; x  
16: (\text{rev} \; \cdot \; \text{rev})x = \text{id} \; x  
17: \text{rev} \; \cdot \; \text{rev} = \text{id}

Once the placement of induction is settled (must text-select both x’s) the rest can be done by double-clicks.
Automated tools such as **ACL2** can be used to do this form of proof on a computer.

**ACL2** = “Applicative Common Lisp 2”

**ACL2** is an interactive theorem prover based on Lisp and structural induction

Originally called the Boyer/Moore Theorem Prover, this designed has been refined continuously since 1970.

See:  
http://www.cs.utexas.edu/users/moore/acl2/
Theorem Prover
Use-Case Diagram

Interactive Theorem Prover

Conjectures and Advice

Proof
ACL2 includes

- **Ordinary** Lisp execution
- **Symbolic** execution (unfolding, rewriting)
- Automated theorem proving
- Formalism for admitting axioms to the system
Sample Function Definition in ACL2

**ACL2** !>

```lisp
(defun app (x y)
    (cond ((endp x) y)
          (t (cons (car x)
                    (app (cdr x) y))))
```

endp checks for the list being empty

The rex equivalent is:

```
app([ ], Y) => Y;
ap([A | X], Y) => [A | app(X, Y)];
```
Sample ACL Ordinary Evaluations

ACL2 !>(app nil '(x y z))
(X Y Z)

ACL2 !>(app '(1 2 3) '(4 5 6 7))
(1 2 3 4 5 6 7)

ACL2 !>(app '(a b c d e f g) '(x y z))
(a b c d e f g x y z)

ACL2 !>(app (app '(1 2) '(3 4)) '(5 6))
(1 2 3 4 5 6)
A theorem that asserts that function app is associative:

ACL2!> (defthm associativity-of-app
   (equal (app (app a b) c)
          (app a (app b c))))
This can be proved using Structural Induction

- \((\text{equal} \ (\text{app} \ (\text{app} \ a \ b) \ c) \ (\text{app} \ a \ (\text{app} \ b \ c))))\)

- In other words,
  \((\forall a)(\forall b)(\forall c) \ \text{app}(\text{app}(a, b), c) = \text{app}(a, \text{app}(b, c))\)

- Exercise: Try proving this by hand.
\textbf{ACL2 Theorem Prover Narrative Output (1)}

\begin{verbatim}
(defthm associativity-of-app
  (equal (app (app a b) c)
         (app a (app b c))))
\end{verbatim}

Name the formula above \textit{*1}.

Perhaps we can prove \textit{*1} by induction. Three induction schemes are suggested by this conjecture. Subsumption reduces that number to two. However, one of these is flawed and so we are left with one viable candidate.

(continued)
We will induct according to a scheme suggested by (APP A B). If we let (:P A B C) denote *1 above then the induction scheme we'll use is

\[
\text{(AND (IMPLIES (AND (NOT (ENDP A)) (:P (CDR A) B C)) (:P A B C)) (IMPLIES (ENDP A) (:P A B C))).}
\]

This induction is justified by the same argument used to admit APP, namely, the measure (ACL2-COUNT A) is decreasing according to the relation E0-ORD-< (which is known to be well-founded on the domain recognized by E0-ORDINALP). When applied to the goal at hand the above induction scheme produces the following two nontautological subgoals.
Subgoal *1/2
(IMPLIES (AND (NOT (ENDP A))
    (EQUAL (APP (APP (CDR A) B) C)
        (APP (CDR A) (APP B C))))
    (EQUAL (APP (APP A B) C)
        (APP A (APP B C))))).

By the simple :definition ENDP we reduce the conjecture to
Subgoal *1/2'
(IMPLIES (AND (CONSP A)
    (EQUAL (APP (APP (CDR A) B) C)
        (APP (CDR A) (APP B C))))
    (EQUAL (APP (APP A B) C)
        (APP A (APP B C)))).

But simplification reduces this to T, using the :definition APP, the :rewrite rules
CDR-CONS and CAR-CONS and primitive type reasoning.
Subgoal *1/1
(IMPLIES (ENDP A)
  (EQUAL (APP (APP A B) C)
    (APP A (APP B C)))).

By the simple :definition ENDP we reduce the conjecture to

Subgoal *1/1'
(IMPLIES (NOT (CONSP A))
  (EQUAL (APP (APP A B) C)
    (APP A (APP B C)))).

But simplification reduces this to T, using the :definition APP and primitive type reasoning.

i.e. True
Using Results

- Once the theorem is proved, it is saved in the system to be used as a **rewrite rule**.

- The system can henceforth rewrite
  
  (app (app x y) z)

  as

  (app x (app y z))
