

information - run in debugger

- debuggers have many valuable features
 - source level (vs machine language)
 - code break points (stop when it gets here)
 - single-stepping (line or instruction at a time)
 - data watch points (stop when it touches this)
 - view and change variables at any time
- invaluable for brute force debugging
 - when you aren't sure what you're looking for
 - run to an interesting point, stop, look around

Bugs and Debugging

8

information – instrumentation

- there isn't always enough information
 - program produces little diagnostic output
 - stack/execution traces are useless
 - detected failure occurs long after the actual error
 - execution in debugger is not practical
 - don't know what code to look at
 - suspect code is called very frequently
- add new instrumentation to program
 - log all conceivably interesting events
 - attempt to reproduce failures w/new version
 - may change symptoms of the failure

4/5/2007

Bugs and Debugging

9

information - forensic analysis

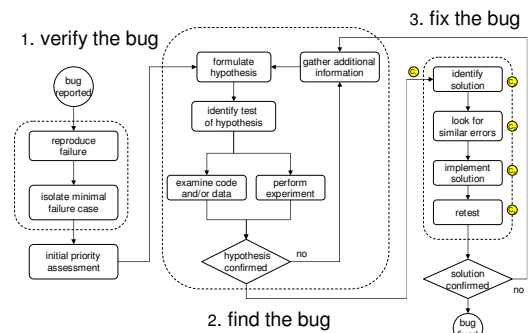

- some problems can be hard to recreate
 - distributed apps often have timing problems
 - pointer errors can have indeterminate results
- some problems have little evidence
 - failure may occur long after the original error
 - most of the evidence is long since gone
- we must infer cause from remaining clues
 - often requires CSI-like detective-work
 - such systems often include diagnostic logs
 - the ultimate fall-back: complete core dump

the scientific debugging process

4/5/2007

Bugs and Debugging

11

reviewing fixes

- original code clearly needed more review
 - original developer did not get it right
 - original reviewers did not find the error
 - original test cases did not find the error
- bug fixes almost always require review
 - correctness of code is clearly not obvious
 - bug fixers are often not original developer
 - they often have less familiarity with the code
 - they often have less programming experience
- how did this get past us before? ●

4/5/2007

Bugs and Debugging

12

Root Cause Analysis

- some bugs may be essentially random ●
 - software is complex, people are fallible
- many bugs turn out not to be random ●
 - people keep repeating the same mistakes
 - inadequate training, tools & methodology
- after a problem has been found and fixed
 - identify the root cause of the defect
 - understand how we made and failed to find it
- do statistical studies of root causes
 - identify clusters, find ways to eliminate them

Bugs and Debugging

13

Psychological Issues

- We assume what we think we know
 - we do not see our work as it actually is
 - rather, we see it as we intended it to be
- We assume we are better than we are
 - we believe in our abilities and methodology
 - we don't like to believe ourselves error-prone
 - we suspect problems come from elsewhere
- These blind us to many hypotheses
 - this blindness impairs our debugging ability

4/5/2007

Bugs and Debugging

14

Becoming a Better Debugger

- Keep an open mind
 - there are none so blind as those who will not see
- Learn from your programming mistakes
 - what did you do wrong?
 - why didn't you notice it sooner?
- Learn from your debugging mistakes
 - what clues were there, but you missed them?
 - what dead-ends did you wind up following?
- Learn from others
 - questions they ask, details they notice
 - tools and techniques do they use

Bugs and Debugging

15

Key Attributes of a Bug Report

- ID (assigned automatically)
- Title (one line description of bug)
- Status
 - current state, severity, priority, owner
- Description
 - suspected component at fault
 - platform, symptoms, how to cause
 - diagnosis, work-arounds, and fix location
- History
 - log of all associated operations & comments

4/5/2007

Bugs and Debugging

16

Bug Report Life Cycle (simplified typical model)

4/5/2007

Bugs and Debugging

17

Good Bug Reports

- Clearly describe the problem
 - what should have happened, what did happen
- Clearly describe the impact
 - consequences to the affected users
- Clearly describe the affected systems
 - what platforms, what versions of what software
- Clearly describe how to cause the problem
 - ideally with a relatively simple test case
 - developing minimal failure cases is work
- Dispassionate, separate facts from opinions

4/5/2007

Bugs and Debugging

18

Bug Tracking Systems

- List of open tasks for developers
 - what work needs to be done
 - communication between developers & users
- Current status of product/development
 - what known problems are there (#, severity)
 - what is the status of each
- Support database
 - known problems and work arounds
- Project management database
 - defect detection rates, fix rates
 - number of problems discovered
 - regression and not-a-bug rates

20

Supplementary Slides

4/5/2007

Bugs and Debugging

21

bug verification

- reproduce the reported error
 - find a test case that reliably causes error
 - it is difficult to fix a problem one cannot observe
 - confirm that we observe reported behavior
 - we may have misunderstood the report
 - enable a preliminary assessment
 - does this, indeed, appear to be an error
- verify that program behavior is wrong
 - problem may be user-error or documentation
 - user may have unreasonable expectations

4/5/2007

Bugs and Debugging

22

minimal failure cases

- some failures are complex or subtle
 - failure occurs after millions of operations
 - failure depends on environmental factors
 - failure isn't always in the same place
- find a simple case that fails solidly
 - isolate the contributing factors
 - find minimal combination that fails reliably
- this makes problem easier to reproduce, and easier to debug

4/5/2007

Bugs and Debugging

23

bug triage

- in emergency, sort patients into 3 groups
 - those who can wait a few hours
 - those who will die no matter what
 - those who need immediate attention
- bugs are prioritized in a similar fashion
 - disastrous bugs, must fix ASAP
 - they render the product unacceptable
 - serious bugs, should fix before shipment
 - they significantly compromise value of the product
 - minor bugs, fixes can be deferred to later

4/5/2007

Bugs and Debugging

24

information - back-traces

- history of all active sub-routine calls
 - an interpreted trace back through stack
 - list of all currently stacked subroutine calls
 - often includes values of parameters
 - may include values of all automatic variables
- tells us, in general, what program is doing
- can generate from core dump after fault
 - e.g. invalid address, zero-divide
- can also be obtained from a debugger

4/5/2007

Bugs and Debugging

25

information - execution traces

- run program under an execution tracer
 - normal instructions execute normally
 - tracer intercepts all system calls
 - logs the system call and its parameters
 - allows OS to execute the system call
 - logs the returned values
 - allows program to continue executing
- fast and simple trace of program activities
 - generates a huge amount of information
 - good idea of what program was doing
